Hardened Reference Ubuntu 18.04 LTS <code>cloud-config</code> :	21

This document provides prescriptive guidance for hardening a production installation of Rancher v2.3.5. It outlines the configurations and controls required to address Kubernetes benchmark controls from the Center for Information Security (CIS).

This hardening guide describes how to secure the nodes in your cluster, and it is recommended to follow this guide before installing Kubernetes.

This hardening guide is intended to be used with specific versions of the CIS Kubernetes Benchmark, Kubernetes, and Rancher:

Hardening Guide Version	Rancher Version	CIS Benchmark Version	Kubernetes Version
Hardening Guide v2.3.5	Rancher v2.3.5	Benchmark v1.5	Kubernetes 1.15

[Click here to download a PDF version of this document](#)

Overview

This document provides prescriptive guidance for hardening a production installation of Rancher v2.3.5 with Kubernetes v1.15. It outlines the configurations required to address Kubernetes benchmark controls from the Center for Information Security (CIS).

For more detail about evaluating a hardened cluster against the official CIS benchmark, refer to the [CIS Benchmark Rancher Self-Assessment Guide - Rancher v2.3.5](#).

Configure Kernel Runtime Parameters

The following `sysctl` configuration is recommended for all nodes type in the cluster. Set the following parameters in `/etc/sysctl.d/90-kubelet.conf`:

```
vm.overcommit_memory=1
vm.panic_on_oom=0
kernel.panic=10
kernel.panic_on_oops=1
kernel.keys.root_maxbytes=25000000
```

Run `sysctl -p /etc/sysctl.d/90-kubelet.conf` to enable the settings.

Configure `etcd` user and group

A user account and group for the `etcd` service is required to be setup prior to installing RKE. The `uid` and `gid` for the `etcd` user will be used in the RKE `config.yml` to set the proper permissions for files and directories during installation time.

create `etcd` user and group

To create the `etcd` group run the following console commands.

```
addgroup --gid 52034 etcd
useradd --comment "etcd service account" --uid 52034 --gid
52034 etcd
```

Update the RKE `config.yml` with the `uid` and `gid` of the `etcd` user:

```
services:
  etcd:
    gid: 52034
    uid: 52034
```

Set `automountServiceAccountToken` to `false` for default service accounts

Kubernetes provides a default service account which is used by cluster workloads where no specific service account is assigned to the pod. Where access to the Kubernetes API from a pod is required, a specific service account should be created for that pod, and rights granted to that service account. The default service account should be configured such that it does not provide a service account token and does not have any explicit rights assignments.

For each namespace the `default` service account must include this value:

```
automountServiceAccountToken: false
```

Save the following yaml to a file called `account_update.yaml`

```

apiVersion: v1
kind: ServiceAccount
metadata:
  name: default
automountServiceAccountToken: false

```

Create a bash script file called `account_update.sh`. Be sure to `chmod +x account_update.sh` so the script has execute permissions.

```

#!/bin/bash -e

for namespace in $(kubectl get namespaces -A -o json | jq -r
'.items[].metadata.name'); do
  kubectl patch serviceaccount default -n ${namespace} -p "$(
cat account_update.yaml)"
done

```

Ensure that all Namespaces have Network Policies defined

Running different applications on the same Kubernetes cluster creates a risk of one compromised application attacking a neighboring application. Network segmentation is important to ensure that containers can communicate only with those they are supposed to. A network policy is a specification of how selections of pods are allowed to communicate with each other and other network endpoints.

Network Policies are namespace scoped. When a network policy is introduced to a given namespace, all traffic not allowed by the policy is denied. However, if there are no network policies in a namespace all traffic will be allowed into and out of the pods in that namespace. To enforce network policies, a CNI (container network interface) plugin must be enabled. This guide uses **canal** to provide the policy enforcement. Additional information about CNI providers can be found [here](#)

Once a CNI provider is enabled on a cluster a default network policy can be applied. For reference purposes a **permissive** example is provide below. If you want to allow all traffic to all pods in a namespace (even if policies are added that cause some pods to be treated as “isolated”), you can create a policy that explicitly allows all traffic in that namespace. Save the following `yaml` as `default-allow-all.yaml`.

Additional [documentation](#) about network policies can be found on the Kubernetes site.

This `NetworkPolicy` is not recommended for production use

```
---
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: default-allow-all
spec:
  podSelector: {}
  policyTypes:
  - Ingress
  - Egress
```

Create a bash script file called `apply_networkPolicy_to_all_ns.sh`. Be sure to `chmod +x apply_networkPolicy_to_all_ns.sh` so the script has execute permissions.

```
#!/bin/bash -e

for namespace in $(kubectl get namespaces -A -o json | jq -r
'.items[].metadata.name'); do
  kubectl apply -f default-allow-all.yaml -n ${namespace}
done
```

Execute this script to apply the `default-allow-all.yaml` the **permissive** `NetworkPolicy` to all namespaces.

Reference Hardened RKE `cluster.yaml` configuration

The reference `cluster.yaml` is used by the RKE CLI that provides the configuration needed to achieve a hardened install of Rancher Kubernetes Engine (RKE). Install [documentation](#) is provided with additional details about the configuration items.

```
# If you intend to deploy Kubernetes in an air-gapped
environment,
# please consult the documentation on how to configure custom
RKE images.
```
